Abstract. Several database areas such as data exchange and integration share the problem of fixing database instance violations with respect to a set of constraints. The chase algorithm solves such violations by inserting tuples and setting the value of nulls. Unfortunately, the chase algorithm may not terminate and the problem of deciding whether the chase process terminates is undecidable. Recently there has been an increasing interest in the identification of sufficient structural properties of constraints which guarantee that the chase algorithm terminates.

In this paper we present more general criteria for chase termination. We first present extensions of the well-known stratification condition and, then, introduce a new criterion, called local stratification (LS), which generalizes both super-weak acyclicity and stratification-based criteria (including the class of constraints which are inductively restricted).

1 Introduction

Several database areas such as data exchange and integration share the problem of fixing database instance violations with respect to a set of constraints [1–6]. The chase algorithm solves such violations by inserting tuples and setting the value of nulls. Unfortunately, the chase algorithm may not terminate and the problem of deciding whether the chase process terminates is undecidable. Recently there has been an increasing interest in the identification of sufficient structural properties of constraints which guarantee that the chase algorithm terminates. Most of these criteria extend weak acyclicity (WA) [7] by analyzing nulls propagation (e.g. the safety criterion (SC) [8]) and constraints firing (e.g. c-stratification (CStr) and inductive restriction (IR) [9], super-weak acyclicity (SwA) [10]).

The idea underlying c-stratification, also used in the IR and SwA criteria, is to consider, in the propagation of nulls, how constraints may fire each other. However, there are simple cases where current criteria are not able to understand that all chase sequences are finite.

Example 1. Consider the following set of constraints $\Sigma_1$ consisting of the TGD

$$\forall x \forall y \ E(x, y) \land E(y, x) \rightarrow \exists z \ E(y, z) \land E(z, x)$$

We can distinguish two cases. If we suppose to have a database instance $D_1 = \{E(a, b), E(b, a)\}$ we have that the TGD is not satisfied, but the constraint will be applied only once by the chase as the resulting database $D'_1 = \{E(a, b), E(b, a)$,
\(E(b, \eta_1), E(\eta_1, a)\) is consistent. Otherwise, if we suppose to have a database instance \(D_2 = \{E(a, a)\}\), it is already consistent, and no chase step will be applied. It is easy to see that the chase is always terminating for all database instances, but none of the existing criteria guaranteeing the termination of all chase sequences is able to recognize it as terminating. \(\square\)

In order to cope with this problem, we first propose a new extension of c-stratification, called \(WA\)-stratification (WA-Str) and then introduce a new criterion, called \(LS\), which generalizes both super-weak acyclicity and inductive restriction. Moreover, both WA-Str and \(LS\) guarantee the termination of all chase sequences, for all database instances, in polynomial time.

## 2 Preliminaries

We introduce the following disjunct sets of symbols: (i) an infinite set \(\text{Consts}\) of constants, (ii) an infinite set \(\text{Nulls}\) of labeled nulls and (iii) an infinite set \(\text{Vars}\) of variables. A relational schema \(R\) is a set of relational predicates \(R\), each with its associated arity \(\text{ar}(R)\). An instance of a relational predicate \(R\) of arity \(n\) is a set of ground atoms in the form \(R(c_1, \ldots, c_n)\), where \(c_i \in \text{Consts} \cup \text{Nulls}\). Such (ground) atoms are also called tuples or facts. We denote by \(D\) a database instance constructed on \(\text{Consts}\) and by \(J, K\) the database instances constructed on \(\text{Consts} \cup \text{Nulls}\). Given an instance \(K\), \(\text{Nulls}(K)\) (resp. \(\text{Consts}(K)\)) denotes the set of labeled nulls (resp. constants) occurring in \(K\). An atomic formula (or atom) is of the form \(R(t_1, \ldots, t_n)\) where \(R\) is a relational predicate, \(t_1, \ldots, t_n\) are terms belonging to the domain \(\text{Consts} \cup \text{Vars}\) and \(n = \text{ar}(R)\).

Given a relational schema \(R\), a tuple generating dependency (TGD) over \(R\) is a formula of the form \(\forall x \phi(x) \rightarrow \exists y \psi(x, y)\), where \(\phi(x, z)\) and \(\psi(x, y)\) are conjunctions of atomic formulas over \(R\); \(\phi(x, z)\) is called the body of \(r\), denoted as \(\text{Body}(r)\), while \(\psi(x, y)\) is called the head of \(r\), denoted as \(\text{Head}(r)\). An equality generating dependency (EGD) over \(R\) is a formula of the form \(\forall x \phi(x) \rightarrow x_1 = x_2\), where \(x_1\) and \(x_2\) are among the variables in \(x\).

In the following we will often omit the universal quantification, since we assume that variables appearing in the body are universally quantified and variables appearing only in the head are existentially quantified. In some cases we also assume that the head and body conjunctions are sets of atoms.

**Definition 1 (Homomorphism [7]).** Let \(K_1\) and \(K_2\) be two instances over \(R\) with values in \(\text{Consts} \cup \text{Nulls}\). A homomorphism \(h : K_1 \rightarrow K_2\) is a mapping from \(\text{Consts}(K_1) \cup \text{Nulls}(K_1)\) to \(\text{Consts}(K_2) \cup \text{Nulls}(K_2)\) such that: (1) \(h(c) = c\), for every \(c \in \text{Consts}(K_1)\), and (2) for every fact \(R_i(t)\) of \(K_1\), we have that \(R_i(h(t))\) is a fact of \(K_2\) (where, if \(t = (a_1, \ldots, a_s)\), then \(h(t) = (h(a_1), \ldots, h(a_s))\)). \(\square\)

Similar to homomorphisms between instances, a homomorphism \(h\) from a conjunctive formula \(\phi(x)\) to an instance \(J\) is a mapping from the variables \(x\) to \(\text{Consts}(J) \cup \text{Nulls}(J)\) such that for every atom \(R(x_1, \ldots, x_n)\) of \(\phi(x)\) the fact \(R(h(x_1), \ldots, h(x_n))\) is in \(J\).

For any database instance \(D\) and set of constraints \(\Sigma\) over a database schema \(R\), a solution for \((D, \Sigma)\) is an instance \(J\) such that \(D \subseteq J\) and \(J \models \Sigma\) (i.e. \(J\) satisfies all constraints in \(\Sigma\)). A universal solution \(J\) is a solution such that for every solution \(J'\) there exists a homomorphism \(h : J \rightarrow J'\). The set of universal solutions for \((D, \Sigma)\) will be denoted by \(\text{USol}(D, \Sigma)\).
Definition 2 (Chase step [7]). Let $K$ be a database instance.

(1) Let $r$ be a TGD $\phi(x, z) \rightarrow \exists y \psi(x, y)$. Let $h$ be a homomorphism from $\phi(x, z)$ to $K$ such that there is no extension of $h$ to a homomorphism $h'$ from $\phi(x, z) \land \psi(x, y)$ to $K$. We say that $r$ can be applied to $K$ with homomorphism $h$. Let $K'$ be the union of $K$ with the set of facts obtained by: (a) extending $h$ to $h'$ such that each variable in $y$ is assigned a fresh labeled null, followed by (b) taking the image of the atoms of $\psi$ under $h'$. We say that the result of applying $r$ to $K$ with $h$ is $K'$, and write $K \xrightarrow{\cdot r} K'$.

(2) Let $r$ be an EGD $\phi(x) \rightarrow x_1 = x_2$. Let $h$ be a homomorphism from $\phi(x)$ to $K$ such that $h(x_1) \neq h(x_2)$. We say that $r$ can be applied to $K$ with homomorphism $h$. More specifically, we distinguish two cases. (a) If both $h(x_1)$ and $h(x_2)$ are in $\text{Consts}$ the result of applying $r$ to $K$ with $h$ is “failure”, and $K \xrightarrow{\cdot r} \perp$. (b) Otherwise, let $K'$ be $K$ where we identify $h(x_1)$ and $h(x_2)$ as follows: if one is a constant, then the labeled null is replaced everywhere by the constant; if both are labeled nulls, then one is replaced everywhere by the other. We say that the result of applying $r$ to $K$ with $h$ is $K'$, and write $K \xrightarrow{\cdot r} K'$.

\[ \Box \]

Definition 3 (Chase [7]). Let $\Sigma$ be a set of TGDs and EGDs, and let $K$ be an instance.

(1) A chase sequence of $K$ with $\Sigma$ is a sequence (finite or infinite) of chase steps $K_i \xrightarrow{\cdot r} K_{i+1}$, with $i = 0, 1, \ldots, K_0 = K$ and $r$ a dependency in $\Sigma$.

(2) A finite chase of $K$ with $\Sigma$ is a finite chase sequence $K_i \xrightarrow{\cdot r} K_{i+1}$, $0 \leq i < m$, with the requirement that either (a) $K_m = \perp$ or (b) there is no dependency $r$ of $\Sigma$ and there is no homomorphism $h_m$ such that $r$ can be applied to $K_m$ with $h_m$. We say that $K_m$ is the result of the finite chase. We refer to case (a) as the case of a failing finite chase and we refer to case (b) as the case of a successful finite chase.

In [7] it has been shown that, for any instance $D$ and set of constraints $\Sigma$: (i) if $J$ is the result of some successful finite chase of $\langle D, \Sigma \rangle$, then $J$ is a universal solution; (ii) if some failing finite chase of $\langle D, \Sigma \rangle$ exists, then there is no solution.

Chase Termination Criteria. We now present a brief overview on the well-known chase termination conditions that guarantee for every database $D$ the termination of all chase sequences in PTIME in the size of $D$. Given a criterion $C$, the class of constraints satisfying $C$ will be denoted by $C$.

Weak acyclicity. Let $\Sigma$ be a set of TGDs over a database schema $R$, then $\text{pos}(\Sigma)$ denotes the set of positions $R_i$ such that $R$ denotes a relational predicate of $R$ and there is an $R$-atom appearing in $\Sigma$. Weak acyclicity (WA) is based on the construction of a directed graph $\text{dep}(\Sigma) = (\text{pos}(\Sigma), E)$, called the dependency graph, where $E$ is defined as follows. For every TGD $\phi(x, z) \rightarrow \exists y \psi(x, y)$ in $\Sigma$, then: i) for every $x$ in $x$ occurring in position $R_i$ in $\phi$ and in position $S_j$ in $\psi$, add an edge $R_i \rightarrow S_j$ (if it does not already exist); ii) for every $x$ in $x$, appearing in position $R_i$ in $\phi$ and for every $y$ in $y$ appearing in position $T_k$ in $\psi$, add a special edge $R_i \rightarrow T_k$ (if it does not already exist). $\Sigma$ is weakly acyclic if $\text{dep}(\Sigma)$ has no cycle going through a special edge.

Safety. The safety condition ($SC$) [9] is based on the notion of affected positions. An affected position denotes a position in which null values may appear,
that is it can also take values from $Nulls$. A position $R_i$ is said to be affected if there is a constraint $r : \phi(x, z) \rightarrow \exists y \psi(x, y)$ in $\Sigma$ and either i) there is a variable $y$ in $y$ appearing in position $R_i$ in $\psi$, or ii) there is a variable $x$ in $x$ appearing both in position $R_i$ in $\psi$ and only in affected positions in the body of $r$. The set of affected positions of $\Sigma$ is denoted by $aff(\Sigma)$.

Given a set of TGDs $\Sigma$, the propagation graph of $\Sigma$, denoted as $prop(\Sigma) = (aff(\Sigma), E')$, is a subset of $dep(\Sigma) = (pos(\Sigma), E)$ such that $E'$ contains the edges in $E$ whose positions are affected (since $aff(\Sigma) \subseteq pos(\Sigma)$). Moreover, $\Sigma$ is said to be safe if $prop(\Sigma)$ does not contain cycles with special edges.

**C-Stratification.** The idea behind $c$-stratification ($CStr$) [11, 9] is to decompose the set of constraints into independent subsets, where each subset consists of constraints that may fire each other, and check each component separately for weak acyclicity. Given a set of constraints $\Sigma$ and two constraints $r_1, r_2 \in \Sigma$, we say that $r_1 \prec_c r_2$ iff there exists a relational database instance $K_1$ and two homomorphisms $h_1$ and $h_2$ such that i) $K_1 \models^{\prec_1} h_1 K_2$, ii) $K_2 \not\models h_2(r_2)$ and iii) $K_1 \models h_2(r_2)$, where the oblivious chase step $K_1 \models h_1 K_2$ states that there is a homomorphism $h_1$ extending $h_1$ which associates every existentially variable $y$ in $h_1(r_1)$ to a fresh labeled null. Intuitively, $r_1 \prec_c r_2$ means that firing $r_1$ can cause the firing of $r_2$. We say that $\Sigma$ is $c$-stratified iff the constraints in every cycle of the $c$-chase graph $G(\Sigma) = (\Sigma, \{r_1, r_2\}|r_1 \prec_c r_2)$ are weakly acyclic.

**Inductive Restriction.** The inductive restriction criterion ($IR$) extends both $CStr$ and $SC$ by partitioning constraints in a more refined way. In particular, it first computes the graph ($G'(\Sigma)$) $\subseteq G(\Sigma)$ and partition $\Sigma$ into $\Sigma_1, ..., \Sigma_n$, where each $\Sigma_i$ is a set of dependencies defining a strongly connected components in $G'(\Sigma)$, next, if $n = 1$ the safety criterion is applied to $\Sigma$, otherwise the $IR$ criterion is applied inductively to each $\Sigma_i$.

**Super-weak acyclicity.** The super-weak acyclicity ($SwA$) [10] builds a trigger graph $\mathcal{T}(\Sigma) = (\Sigma, E)$ where edges define relations among constraints. An edge $r_i \sim r_j$ means that a null value introduced by a constraint $r_i$ is propagated (directly or indirectly) into the body of $r_j$.

Let $\Sigma$ be a set of TGDs and let $sk(\Sigma)$ be the logic program obtained by skolemizing $\Sigma$, i.e. by replacing each existentially quantified variable $y$ appearing in the head of a TGD $r$ by the skolem function $f_y^r(\mathbf{x})$, where $\mathbf{x}$ is the set of variables appearing both in the body and in the head of $r$. A place is a pair $(a, i)$ where $a$ is an atom of $sk(\Sigma)$ and $0 \leq i \leq ar(a)$. Given a TGD $r$ and an existential variable $y$ in the head of $r$, $Out(r, y)$ denotes the set of places (called output places) in the head of $sk(r)$ where a term of the form $f_y^r(\mathbf{x})$ occurs. Let $r$ be a TGD $r$ and let $x$ be a universal variable of $r$, $In(r, x)$ denotes the set of places (called input places) in the body of $r$ where $x$ occurs.

Given a set of variables $V$, a substitution $\theta$ of $V$ is a function mapping each $v \in V$ to a finite term $\theta(v)$ built upon constants and function symbols. Two places $(a, i)$ and $(a', i)$ are unifiable and we write $(a, i) \sim (a', i)$ iff there exist two substitutions $\theta$ and $\theta'$ of (respectively) the variables $a$ and $a'$ such that $a[\theta] = a'[\theta']$. Given two sets of places $Q$ and $Q'$ we write $Q \subseteq Q'$ iff for all $q \in Q$ there exists some $q' \in Q'$ such that $q \sim q'$.

For any set $Q$ of places, $Move(\Sigma, Q)$ denotes the smallest set of places $Q'$ such that $Q \subseteq Q'$, and for every constraint $r = B_r \rightarrow H_r$ in $sk(\Sigma)$ and every
variable $x$, if $\Pi_x(B_r) \subseteq Q'$ then $\Pi_x(H_r) \subseteq Q'$, where $\Pi_x(B_r)$ and $\Pi_x(H_r)$ denote the sets of places in $B_r$ and $H_r$ where $x$ occurs.

Given a set $\Sigma$ of TGDs and two TGDs $r_1, r_2 \in \Sigma$, we say that $r_1$ triggers $r_2$ in $\Sigma$ and write $r_1 \Rightarrow r_2$ iff there exists an existential variable $y$ in the head of $r_1$, and a universal variable $x_2$ occurring both in the body and head of $r_2$ such that $In(r_2, x_2) \subseteq Move(\Sigma, Out(r_1, y))$. A set of constraints $\Sigma$ is super-weakly acyclic iff the trigger graph $\Upsilon(\Sigma) = (\Sigma, \{(r_1, r_2)|r_1 \Rightarrow r_2\})$ is acyclic. W.r.t. other criteria, $SwA$ also takes into account that a variable may occur more than once in the same atom. $SwA$ extends $SC$, but is not comparable with $CStr$.

3 WA-Stratification

We start by introducing some improvements for the $c$-stratification criterion. First of all, observe that $c$-stratification does not specify what kind of cycles are checked (i.e. simple or general) [12]. Checking simple cycles is not correct as it may not consider all possible chase sequences, but checking general cycles, means that for each strongly connected component there is one cycle including all nodes in the component which subsumes all other cycles on the same component (in terms of constraints to be considered). Thus, a first observation on ($c$-)stratification (in terms of correctness, if simple cycles are considered, or in terms of efficiency, if all cycles are considered) is that it refers to cycles instead of strongly connected components. A further observation is that it uses oblivious chase for checking termination of standard chase and its applicability is limited.

**Definition 4 (WA-Stratification).** Given a set of dependencies $\Sigma$ and $r_1, r_2 \in \Sigma$, we say that $r_1 < r_2$ iff there exist a relational database instance $K$, homomorphisms $h_1, h_2$ and a set $S$ of atoms, such that

1. $K_1 \nvdash h_1(r_1)$,
2. $K_1 \vdash h_1(r_1) \land K_2$, 
3. $K_1 \cup S \vdash h_2(r_2)$, 
4. $K_2 \cup S \nvdash h_2(r_2)$ and 
5. $Null(S) \cap (Null(K_2) - Null(K_1)) = \emptyset$ (i.e. $S$ does not contain new null values introduced in $K_2$).

We say that $\Sigma$ is WA-stratified ($WA-Str$) iff the constraints in every nontrivial strongly connected component of the firing graph $\Gamma(\Sigma) = (\Sigma, \{(r_1, r_2)|r_1 < r_2\})$ are weakly acyclic.

With respect to $c$-stratification, $WA-Str$ also considers in the satisfaction of constraint $r_2$, in addition to the database $K_1$, a set of atoms $S$ (cond. (3)) and atoms in $S$ cannot contain null values introduced in the application of the constraint $r_1$ (cond. (5)). Moreover, since we are considering strongly connected components (instead of cycles) these components must not be trivial, that is they must have at least one edge, otherwise the constraint cannot be fired cyclically. As a further important observation, in the above definition we consider standard chase for both constructing the graph $\Gamma(\Sigma)$ and checking weak acyclicity.

**Example 2.** Consider again the set of constraints $\Sigma_1$ of Example 1. It is easy to see that, by considering standard chase, does not exist an initial database instance such that the constraint can fire itself, while, by considering the oblivious chase, the constraint fires itself ad infinitum. Thus, the set of constraints $\Sigma_1$ is WA-stratified, but not $c$-stratified.
The following proposition states that WA-Str criterion is more general than CStr and is not comparable with SC. Consequently it is not comparable even with SwA as SC is strictly contained in SwA and CStr is not comparable with SwA.

**Proposition 1.** $\text{CStr} \subsetneq \text{WA-Str}$ and $\text{SC} \parallel \text{WA-Str}$.  

It is important to observe that WA-Str criterion could be improved by testing safety instead of weak acyclicity over the firing graph. Further improvements could be obtained by considering super-weak acyclicity instead of safety.

**Definition 5 (SC-Stratification and SwA-Stratification).** Given a set of TGDs $\Sigma$, we say that (1) $\Sigma$ is SC-stratified ($\text{SC-Str}$) if the constraints in every strongly connected component of the firing graph $\Gamma(\Sigma)$ are safe, and (2) $\Sigma$ is SwA-stratified ($\text{SwA-Str}$) if the constraints in every strongly connected component of the firing graph $\Gamma(\Sigma)$ are super-weak acyclic.

We now analyze the complexity of the above criteria starting by defining a bound on the complexity of the firing problem, i.e. the complexity of checking whether $r_1 < r_2$.

**Lemma 1.** Let $r_1 : \phi_1 \rightarrow A_1 \land \cdots \land A_k$ and $r_2 : B_1 \land \cdots \land B_n \rightarrow \psi_2$ be two TGDs. The problem of checking whether $r_1 < r_2$ is bounded by $O((k + 1)^n)$.  

Although the theoretical complexity of the "firing" problem is exponential, in most cases it is very low (e.g. inclusion dependencies, multivalued dependencies [13]), as usually the number $n$ of body atoms in the fired constraint $r_2$ is small and the number of atoms in the head of constraint $r_1$ which could be used to fire $r_2$ through their unification with $B_i$ (i.e. $k_i > 1$) is even smaller. Indeed, if the number of atoms in the body of $r_2$ is bounded by a constant, the firing problem is in PTIME. Significative subclasses of constraints for which the firing problem becomes polynomial could be identified, but this is not the aim of this paper.

In the following, for a given set of constraints $\Sigma$, we shall denote with $C_{ij}$ the complexity of the problem of checking whether $r_i < r_j$, for $r_i, r_j \in \Sigma$, and with $C_m = \max \{C_{ij}|r_i, r_j \in \Sigma\}$.

**Proposition 2.** Let $\Sigma$ be a set of TGDs, $D$ be a database Then:
- the problem of checking whether $\Sigma$ is WA-stratified (resp. SC-stratified, SwA-stratified) is bounded by $O(C_m \times |\Sigma|^2)$;
- if $\Sigma$ is WA-stratified (resp. SC-stratified, SwA-stratified), the length of every chase sequence of $\Sigma$ over $D$ is polynomial in the size of $D$.  

The class of constraints satisfying criterion $\text{C-Str}$, for $C \in \{\text{WA, SC, SwA}\}$, will be denoted by $\text{C-Str}$. The next theorem states the relationships among the above mentioned criteria and other previously defined conditions.

**Theorem 1.**

1. $\text{WA-Str} \subsetneq \text{SC-Str} \subsetneq \text{SwA-Str}$,
2. for $C \in \{\text{WA, SC, SwA}\}$, $C \not\sqsubset \text{C-Str}$ and
3. $\text{SR} \parallel \text{SwA-Str}$ and $\text{IR} \parallel \text{SwA-Str}$.

4 Local Stratification

It is trivial that more powerful criteria could be defined by composing criteria which are not comparable. We next present a different generalization of super-weak acyclicity which also generalizes the class \(\mathcal{TR}\).

We start by introducing a notion of fireable place. We say that a place \(q\) appearing in the body of constraint \(r\) could be fired by a place \(q'\) appearing in the head of constraint \(r'\), denoted by \(q' < q\), if \(q \sim q'\) and \(r' < r\). Given two sets of places \(Q\) and \(Q'\) we say that \(Q\) could be fired by \(Q'\), denoted by \(Q' < Q\) iff for all \(q \in Q\) there exists some \(q' \in Q'\) such that \(q' < q\).

Given a set \(Q\) of places, we define \(\text{MOVE}(\Sigma, Q)\) as the smallest set of places \(Q'\) such that \(Q \subseteq Q'\), and for every constraint \(r = B_r \rightarrow H_r\) in \(\text{sk}(\Sigma)\) and every variable \(x\), if \(Q' < \Pi_x(B_r)\) then \(\Pi_x(H_r) \subseteq Q'\), where \(\Pi_x(B_r)\) and \(\Pi_x(H_r)\) denote the sets of places in \(B_r\) and \(H_r\) where \(x\) occurs.

With respect to the function \(\text{Move}\), the new function \(\text{MOVE}\) here considered takes into account the firing of places and not only the unification of places.

**Definition 6 (Local Stratification).** Given a set \(\Sigma\) of TGDs and two TGDs \(r_1, r_2 \in \Sigma\), we say that \(r_1\) triggers \(r_2\) in \(\Sigma\) and write \(r_1 \leftrightarrow r_2\) iff there exists an existential variable \(y\) in the head of \(r_1\), and a universal variable \(x\) occurring both in the body and head of \(r_2\) such that \(\text{MOVE}(\Sigma, \text{Out}(r_1, y)) < \text{In}(r_2, x)\).

A set of constraints \(\Sigma\) is **locally stratified** (LS) iff the trigger graph \(\Delta(\Sigma) = \{(r_1, r_2) | r_1 \leftrightarrow r_2\}\) is acyclic.

**Proposition 3.** For every set of TGDs \(\Sigma\) and for every database \(D\)
- the problem of checking whether \(\Sigma\) is locally stratified is bounded by \(O(C_m \times |\Sigma|^2)\);
- if \(\Sigma\) is locally stratified, the length of every chase sequence of \(\Sigma\) over \(D\) is polynomial in the size of \(D\).

The below theorem states that the class of locally stratified constraints (denoted by \(\mathcal{LS}\)) is more general than \(\mathcal{SwA-Str}\) and \(\mathcal{IR}\).

**Theorem 2.** \(\mathcal{SwA-Str} \nsubseteq \mathcal{LS}\) and \(\mathcal{IR} \nsubseteq \mathcal{LS}\).

The next example shows that the containment of \(\mathcal{SwA-Str} \cup \mathcal{IR}\) in \(\mathcal{LS}\) is strict.

**Example 3.** The following set of constraints \(\Sigma_3\) is locally stratified, but it is neither super-weakly acyclic nor inductively restricted:

\[
\begin{align*}
    r_1 & : N(x) \rightarrow \exists y \exists z \ E(x, y) \land S(z, y) \\
    r_2 & : E(x, y) \land S(x, y) \rightarrow N(y) \\
    r_3 & : E(x, y) \rightarrow E(y, x)
\end{align*}
\]

Considering \(\mathcal{SwA}\), we have that \(\text{Move}(\Sigma, \text{Out}(r_1, y)) = \{p_3, p_5, p_{10}, p_{13}, p_2, p_{14}\}\) and \(\text{In}(r_1, x) = \{p_1\} \subseteq \text{Move}(\Sigma, \text{Out}(r_1, y))\). The trigger graph is cyclic as \(r_1 \sim r_1\) and, therefore, \(\Sigma_3\) is not super-weakly acyclic. As \(r_1 < r_3 < r_2 < r_1\) we have that \(\Sigma_3\) is not \(\mathcal{SwA-Str}\) as well. \(\Sigma_3\) is not \(\mathcal{IR}\) as \(r_1 \ll r_3 \ll r_2 \ll r_1\) and for each pair of constraints \(r_i, r_j\) such that \(r_i \ll r_j\), it is possible to construct a database containing null values in positions \(E_1, E_2, N_1\) and \(S_2\) such that whenever \(r_i\) fires \(r_j\) a null value is propagated from the head of \(r_i\) to the head of \(r_j\).

Moreover, as \(r_1 \not\sim r_1\) \(\text{MOVE}(\Sigma, \text{Out}(r_1, y)) = \{p_3, p_5, p_{13}\}\) and \(\text{In}(r_1, x) = \{p_1\} \subseteq \text{MOVE}(\Sigma, \text{Out}(r_1, y))\), \(\Delta(\Sigma_3)\) is acyclic and, thus, \(\Sigma_3\) is locally stratified.
5 Conclusions

In this paper we have proposed new criteria for checking chase termination on the base of constraints structural properties. We have shown that the local stratification criterium here introduced, strictly generalize criteria previously proposed in the literature. The relationships among previous criteria and the ones here proposed are reported in Figure 1.
